

VMware Attack Simulation and Live Monitoring Setup

The main objective of this ticket is to simulate real cyberattacks inside a controlled virtual environment using VMware Workstation. The objective was to understand how attacks are generated, detected, monitored, and analyzed using Ubuntu Linux virtual machines and a live monitoring system.

HOW I HAVE DONE

In this task, I needed to install VMware and create two Linux workstations. I chose Ubuntu because I have some knowledge in it.

First, I have installed VMWARE WORKSTATION AND UBUNTU ISO FILE

I HAVE CREATED TWO UBUNTU WORKSTATIONS IN IT AND NAMED THEM AS VM1 AND VM2

Here, I have connected VM1 with my Digital Fort live monitor with API key. From VM2, I have simulated attacks on VM2, and the attacks are observed from the live monitor.

BLOCKERS FACED

Creating virtual machine workshop (VM2) was difficult because of my RAM and storage issues.

I have tried so many ways to create VM2 but I failed. After that, I took help from my co-interns and successfully created the VM2 and worked on it.

STEPS PERFORMED IN THIS TASK

- VMWARE, UBUNTU ISO FILE INSTALLATION
- CREATING TWO UBUNTU VIRTUAL MACHINES
- CONNECTING TO DIGITAL FORT CONTAINER
- ATTACK SIMULATION
- ANALYSING ON LIVE MONITOR
